Fingerprint Sensor

Description
The CXA3621GE is an electrostatic capacitance method fingerprint sensor.
This monolithic IC integrates the sensor block, sense amplifier (3-bit gain adjustment), sample-and-hold, output amplifier and output buffer needed to acquire fingerprint images, as well as the timing generator for determining the operation of these functions onto a single chip.

Features
• Electrostatic capacitance type sensor (charge transfer method)
• Number of pixels: 192 × 128
• 317 DPI
• Low power consumption (50mW or less) * When P/S: 18µW or less
• Single 3.0V power supply
• Sensor gain control: 3 bits
• S/N ratio improved by on-chip sensor block parasitic capacitance cancel function

Applications
Fingerprint verification units

Structure
Silicon gate CMOS IC

Absolute Maximum Ratings (Ta = 25°C)
• Supply voltage AVDD, DVDD VSS – 0.5 to +7.0 V
• Input voltage VI VSS – 0.5 to VDD + 0.5 V
• Output voltage VO VSS – 0.5 to VDD + 0.5 V
• Operating temperature Topr –20 to +75 °C
• Storage temperature Tstg –25 to +125 °C
• Allowable power dissipation PD 1100 mW

Recommended Operating Conditions
• Supply voltage AVDD, DVDD 2.7 to 3.6 V
• Ambient operating temperature Ta 0 to +50 °C

*1 Output voltage Air Level means the output level in the condition where nothing is placed against the sensor surface (in other words, in air). This rating value is obtained by measuring 32 points within one line of the sensor output and then taking the average.

The gain setting for this measurement is (011).

*2 Output voltage Water Level specifies the degree to which the output level changes from the Air Level when a drop of water is placed on the sensor surface. However, it is unrealistic to place a drop of water on each sensor surface when sorting products, so 32 virtual capacitors (parasitic capacitance equal to the level when a drop of water is placed on the surface) are built into the sensor chip, and the average of these output values is calculated. The difference from the Air Level noted above becomes the Water Level.

The gain setting for this measurement is (011).
Electrical Characteristics Measurement Circuit

The load of 30pF or more is added to each pin.
Application Circuit

Application circuits shown are typical examples illustrating the operation of the devices. Sony cannot assume responsibility for any problems arising out of the use of these circuits or for any infringement of third party patent and other right due to same.
Description of Operation

- **Fingerprint sensor principle**
  The principle of this newly developed fingerprint sensor is described below (Fig. 1). The sensor block contains an array of metal electrodes which are covered on top by an insulating film (overcoat). When a finger (which is conductive matter) is placed directly against this surface, the three elements of the metal electrode, the insulating film and the finger form a capacitor.
  The difference between the fingerprint ridges and valleys is the difference in distance to the metal electrodes, and becomes the difference in the capacitance values of the individually formed capacitors. (The ridge capacitance values are determined by the dielectric constant of the insulating film, but the valleys contain air in addition to this, making the difference between the ridge and valley capacitance values even greater than the difference in distance.)
  Using this principle, by applying a constant voltage to all metal electrodes, the charge level accumulated in each electrode differs, making it possible to output the unevenness of the fingerprint as an electric signal by transferring and converting these charges to voltages.

![Fig. 1](image-url)
**Fingerprint sensor operation (Fig. 2)**

Description of characters

- **Cs:** Capacitance formed between the finger and the metal electrode
- **Cp:** Parasitic capacitance formed between the metal electrode and the silicon substrate
- **Cp':** Capacitance for canceling Cp (Cp = Cp')
- **Ch:** Hold capacitance
- **Cf:** Feedback capacitance for determining the gain
- **S:** Switch
- **V:** Node voltage

Notes on Operation

Sensor surface electrostatic strength
Aerial discharge (150pF, 330Ω): ±12kV or more

Sony conducts tests using the 50% flash-over method* from the viewpoint of reproducibility and comparison of performance. This method allows more stable measurement than the general method of approaching a discharge gun (approach method). However the discharge distance tends to be longer than for the approach method, so the above performances may not be satisfied if testing is performed by the approach method.

*The discharge distance (distance between the probe tip and the test piece) is determined, and a trigger is applied at fixed time intervals to raise the applied voltage and start discharge. The applied voltage when discharge occurs at just 1/2 of the number of trigger times is the 50% flash-over voltage. The flash-over voltage changes when the distance is changed, but it has been confirmed that there are no problems in terms of sensor performance up to ±12kV.

Sensor surface strength
The sensor surface may be broken by the contact of the metal and others. Therefore, be sure to pay the sufficient attention to handling this IC.

*Never handle sensors with metal tweezers or similar tools on mounting lines, etc.
